**Assessing the Effect of Dirt on Performance of Engine Cooling System** Jul 20 2022 The radiator plays a very important role in an automobile. It dissipates the waste heat generated after the combustion process and useful work has been done to prevent engine overheating. The effectiveness with which waste heat is transferred from the engine walls to the surrounding is crucial in preserving the material integrity of the engine and enhancing the performance of the engine. This book looked at the effect of sand blocking the heat transfer area of the radiator and its effect on the engine coolant through the conduct of experiments and a mathematical model developed. This book shed some light on the radiator modeling using Matlab simulation to assess the effect of dirt on the blockage of the radiator on the performance of an engine cooling system. This book provide useful information for all Engineers or anyone else who may be using vehicle and are interesting in knowing more about radiator and Engine Cooling System.

**Development of Model for Large-bore Engine Cooling Systems** Nov 12 2021 The purpose of this thesis is to present on the development and results of the cooling system logic tree and model developed as part of the Pipeline Research Council International, Inc (PRCI) funded project at the Kansas State National Gas Machinery Laboratory. PRCI noticed that many of the legacy engines utilized in the natural gas transmission industry were plagued by cooling system problems. As such, a need existed to better understand the heat transfer mechanisms from the combusting gases to the cooling water, and then from the cooling water to the environment. To meet this need, a logic tree was developed to provide guidance on how to balance and identify problems within the cooling system and schedule appropriate maintenance. Utilizing information taken from OEM operating guides, a cooling system model was developed to supplement the logic tree in providing further guidance and understanding of cooling system operation. The cooling system model calculates the heat loads experienced within the engine cooling system, the pressures within the system, and the temperatures exiting the cooling equipment. The cooling system engineering model was developed based upon the fluid dynamics, thermodynamics, and heat transfer experienced by the coolant within the system. The inputs of the model are familiar to the operating companies and include the characteristics of the engine and coolant piping system, coolant chemistry, and engine oil system characteristics. Included in the model are the various components that collectively comprise the engine cooling system, including the water cooling pump, aftercooler, surge tank, fin-fan units, and oil cooler. The results of the Excel-based model were then compared to available field data to determine the validity of the model. The cooling system model was then used to conduct a parametric investigation of various operating conditions including part vs. full load and engine speed, turbocharger performance, and changes in ambient conditions. The results of this parametric investigation are summarized as charts and tables that are presented as part of this thesis.

*High-Performance Automotive Cooling Systems* Nov 24 2022 When considering how well modern cars perform in many areas, it is easy to forget some of the issues motorists had on a regular basis 40+ years ago. Cars needed maintenance regularly: plugs and points had to be replaced on a frequent basis, the expected engine life was 100,000 miles rather than double and triple the expectation that you see today, and an everyday hassle, especially in warm climates, was being the victim of an overheating car. It was not uncommon on a hot day to see cars stuck in traffic, spewing coolant onto the ground with the hoods up in a desperate attempt to cool off. Fast-forward to today, and it's easy to forget that modern cars even have coolant. The temp needle moves to where it is supposed to be and never moves again until you shut the car off. For drivers of vintage cars, this level of reliability is also attainable. In High-Performance Automotive Cooling Systems, author Dr. John Kershaw explains the basics of a cooling system operation, provides an examination of coolant and

radiator options, explains how to manage coolant speed through your engine and why it is important, examines how to manage airflow through your radiator, takes a thorough look at cooling fans, and finally uses all this information in the testing and installation of all these components. Muscle cars and hot rod engines today are pushed to the limit with stroker kits and power adders straining the capabilities of your cooling system to extremes never seen before. Whether you are a fan of modern performance cars or a fan of more modern performance in vintage cars, this book will help you build a robust cooling system to match today's horsepower demands and help you keep your cool.

**Energy Optimization Using Model Predictive Control for Engine Cooling Systems in Heavy Duty Trucks** Apr 24 2020 To comply with stringent emission and fuel consumption standards, manufacturers in the automotive industry have strived to improve the fuel economy of their vehicles through the advancements in the powertrain, drivetrain, and aerodynamics. Improvements in the fuel economy can also be obtained from reducing the auxiliary load exerted on the engine from components such as the alternator, water pumps, and radiator fan. The engine cooling system contributes to the auxiliary loads by utilizing components, such as the water pump and radiator fan, to control the temperature of the engine. This Thesis investigates the fuel economy improvements in the engine cooling system for heavy-duty trucks by designing a predictive control strategy for the radiator fan. First, a model of the engine cooling system is derived and validated through experimental tests. Then, an optimal control problem is formulated with the objective of optimizing two performance metrics: 1) vehicle fuel consumption including auxiliaries and 2) the coolant temperature tracking performance. Due to the nonlinearities in the system, Dynamic Programming (DP) is used as the solution algorithm. Once the analysis of the DP solution is performed and a benchmark is governed, a real-time implementable strategy is developed using Model Predictive Control (MPC). The advantage of MPC, namely optimality while satisfying constraints, can be exploited further in the framework of Connected and Automated Vehicles (CAVs), where information on future driving conditions become available. In this Thesis, the optimal fan control for a connected truck is developed and tested in multiple environments, such as Software-in-the-Loop and Engine-in-the-Loop. The proposed predictive control strategy has obtained average fuel savings of 1.84% through Engine-in-the-Loop testing.
